Abstract

Background: Autism disorders which are also known pervasive developmental disorders as are very complex and heterogeneous group of chronic disorders that marked by early impairment in socialization, communication, and behavior. Although the occurrence of self-injurious behaviors has been reported as early as the 1970s, this association has not been adequately emphasized.

Patients and methods: The case of a 3.5-year Iraqi boy who has autism disorder and self injurious behaviors is described.

Results: A 3.5-year Iraqi boy was seen because of poor communication with others and poor speech development. At the clinic, the boy was not responding to name and had no eye contact, and it was like the doctor was not visible to him at all. He was also hyperactive and was trying to leave the room. The parents were also concerned about biting his hand especially when wanted to go outside home and the family prevented him.

The diagnosis of typical autism without significant mental retardation was made and the patient was initially treated with courses of intramuscular cerebrolysin based on our extensive published experiences with treatment of autism disorders.

Conclusion: In this paper, the association of self-injurious behavior with autism disorder is emphasized, and the uncommon occurrence in association with autism sis order without significant mental retardation is described.

Keywords: Self injury, autism, cerebrolysin, educational article.
Introduction

Autism disorders, which are also known pervasive developmental disorders as are very complex and heterogeneous group of chronic disorders that marked by early impairment in socialization, communication, and behavior. Autism disorders were first recognized by Grunya Efimovna Sukhareva (Figure-1A), a Soviet pediatric psychiatrist in 1925, and she called these disorders autistic psychopathy.

Figure-1A: Grunya Efimovna Sukhareva, a Soviet pediatric psychiatrist

The characteristic and diagnostic manifestations of autism disorders result from impairments in social interaction and communication. The impaired social interaction causes the two major diagnostic features of autism which are the lack of eye contact, and the lack of appropriate responsiveness to own name. Difficulties in using and understanding language are an important feature of autism disorders. Repetitive body movements or behavior patterns including hand flapping, foot tapping, and spinning are commonly associated with autism disorders.

The Autistic disorder which is called classical autism was first described by Leo Kanner (Figure-1B) in 1943. The diagnostic feature of this type is normal or high intelligence.

Figure-1B: Leo Kanner

Children with Autism disorder who have subnormal intelligence, but without significant mental retardation are considered to have typical autism. The absence of significant mental retardation in such children is suggested by having acceptable adaptive behaviors including eating with spoon, bowel control and going to bathroom. In children with typical autism disorder, the serious lack of communication skills per se is expected to prevent or delay the acquisition of developmental milestones.

Asperger syndrome was first described by Grunya Efimovna Sukhareva, and later by Hans Asperger (Figure-1C) in 1944 [1-7].
Although the occurrence of self-injurious behaviors has been reported as early as the 1970s, this association has not been adequately emphasized [8].

Patients and methods
The case of a 3.5-year Iraqi boy who has autism disorder and self-injurious behaviors is described.

Results
A 3.5-year Iraqi boy was seen because of poor communication with others and poor speech development. At home he was not responding to name and had very poor eye contact (Figure-2A). He was also having repetitive movements and was sometimes hitting the floor until experiencing pain (Figure-2B). He was repeating many words taught by his mother but was not using them satisfactorily to express his needs or to communicate with others.
Figure-2B: The boy had repetitive movements and was sometimes hitting the floor until experiencing pain

He was still unable to go the toilet by his own, and the parents were satisfied by his self-feeding ability (Figure-2C) despite he was eating sometimes things like rice by his hands and not using a spoon. He could use the pen to draw scribble and lines and some circular figures that are not that good (Figure-2D).

Figure-2C: The parents were satisfied by his self-feeding ability
At the clinic, the boy was not responding to name and had no eye contact (Figure-3), and it was like the doctor was not visible to him at all. He was also hyperactive and was trying to leave the room.

The parents were also concerned about biting his hand especially when wanted to go outside home and the family prevented him.

The diagnosis of typical autism without significant mental retardation was made and the patient was initially treated with courses of intramuscular cerebrolysin based on our extensive published experiences with treatment of autism disorders [9-15].

**Discussion**

Self-injury is a serious behavioral abnormality that is commonly reported in association with severe mental retardation, and it occurrence in association with autism without significant mental retardation is uncommon [5, 8, 16, 17, 18, 19, 20].

Recently, Malhi and Sankhyan (2021) studied the records of 1252 children with autism disorders and reported that about 22 % had self injurious behavior including head banging (47%), and self hitting (27.8%) [21].

Neufeld and Fantuzzo (1984) suggested the use of a protective plastic mouth shielding apparatus in the...
treatment of children with autism and severe self-biting behavior [18].
Gedye (1990) reported that trazodone reduced self-injurious and aggressive behaviors in a male patient with autism and mental retardation [21].
McCracken et al (2002) reported a placebo controlled, double-blind study of the use of risperidone in the treatment of 101 children (82 boys and 19 girls) aged 5 to 17 years, having autism disorder associated with severe tantrums, aggression, or self-injurious behavior. The study found that risperidone was beneficial for the treatment of tantrums, aggression, or self-injurious behavior in children, and was well tolerated [24].
This patient was initially treated with courses of intramuscular cerebrolysin based on our extensive published experiences with treatment of autism disorders [9-15].
Cerebrolysin, a safe parenteral mixture of aminoacids which has been used with a benefit in a variety of childhood neuropsychiatric disorders, is the only medical therapy that is known to be associated with significant improvement and even cure of the major autistic features (Poor response to name and poor eye contact which indicate impaired communication) [9-15].
In this paper, the association of self-injurious behavior with autism disorder is emphasized, and the uncommon occurrence in association with autism disorder without significant mental retardation is described.
